Abstract

We present a boundary feedback law that stabilizes the velocity, pressure, and electromagnetic fields in a magnetohydrodynamic (MHD) channel flow. The MHD channel flow, also known as Hartmann flow, is a benchmark for applications such as cooling, hypersonic flight and propulsion. It involves an electrically conducting fluid moving between parallel plates in the presence of an externally imposed transverse magnetic field. The system is described by the inductionless MHD equations, a combination of

the Navier-Stokes equations and a Poisson equation for the electric potential under the MHD approximation in a low magnetic Reynolds number regime. This model is unstable for large Reynolds numbers, and is stabilized by actuation of velocity and the electric potential at only one of the walls. The backstepping method for stabilization of parabolic PDEs is applied to the velocity field system written in appropriate coordinates. Control gains are computed by solving a set of linear hyperbolic PDEs. Stabilization of non-discretized 3-D MHD channel flow has so far been an open problem.

Nomenclature

\( j \) Electric current.
\( k_x, k_y \) Wave numbers.
\( K, \Gamma_1, \Gamma_2 \) Control kernels.
\( H \) Hartmann number.
\( N \) Stuart number.
\( P \) Pressure.
\( p \) Pressure fluctuation.
\( Re \) Reynolds number.
\( Re_M \) Magnetic Reynolds number.
\( U \) Streamwise velocity.
\( U^e \) Streamwise equilibrium velocity.
\( U_C \) Streamwise velocity controller.
\( u \) Streamwise velocity fluctuation.
V  Wall-normal velocity.

V_C  Wall-normal velocity controller.

W  Spanwise velocity.

W_C  Spanwise velocity controller.

\phi  Electric potential.

\Phi_C  Electric potential controller.

\Lambda  Lyapunov function.

1  Introduction

In this paper, we derive an explicit boundary controller that stabilizes an incompressible magnetohydrodynamic (MHD) flow in an infinite rectangular 3-D channel. Known as the Hartmann flow [1], this model is considered a benchmark for applications such as liquid-metal cooling of nuclear reactors and supercomputers, plasma confinement, electromagnetic casting, hypersonic flight and propulsion.

In the Hartmann flow, an electrically conducting fluid (such as a liquid metal, a plasma or salt water) moves between parallel plates and is affected by an imposed transverse magnetic field. The movement of a conducting fluid produces an electric field and subsequently an electric current. The interaction between this current and the external magnetic field induces a body force, called the Lorentz force, which acts on the fluid itself. Hence the velocity and electromagnetic fields are highly coupled. These fields are mathematically described by the MHD equations [2], which are the Navier-Stokes equation coupled with the Maxwell equations.
In the non-conducting case, the geometry we consider (channel flow) is known to be unstable for high Reynolds numbers and has been thoroughly studied and is frequently cited as a paradigm for transition to turbulence [3]. There are many works in flow control that consider the problem of channel flow stabilization, for instance, using optimal control [4], backstepping [5, 6], spectral decomposition/pole placement [7], Lyapunov design/passivity [8, 9], or nonlinear model reduction/in-domain actuation [10].

The stability of the Hartmann flow has also been extensively studied, both from the numerical and the analytical point of view [11, 12, 13, 14]. However, specific results on stabilization of magnetohydrodynamic flows are more scarce. Prior works focus mainly on electro-magneto-hydro-dynamic (EMHD) flow control in weak electrically conducting fluids such as saltwater. Traditionally two types of actuator designs have been used: one type generates a Lorentz field parallel to the wall in the streamwise direction [15], while the other one generates a Lorentz field normal to the wall in the spanwise direction [16, 17]. EMHD flow control has been dominated by strategies that either permanently activate the actuators or pulse them at arbitrary frequencies. However, it has been shown that feedback control schemes can improve the efficiency, by reducing control power, for both streamwise [18] and spanwise [19, 20] approaches. Other recent developments use model-based techniques, for instance using nonlinear model reduction [21, 22] or optimal control [23].

There are some experimental results available as well, showing the feasibility of MHD flow control; actuators consist of magnets and electrodes [16, 17, 24], for instance electromagnetic tiles [25]. Mathematical studies of controllability of magnetohydrodynamic flows have been done, though they do not provide explicit controllers [26, 27].

Applications include drag reduction [16, 20], boundary layer control [25, 28], mixing.
enhancement for cooling systems [29, 30], turbulence control [31], or estimation of velocity, pressure and electromagnetic fields [32].

This paper uses the backstepping method and extends our previous work for stabilization of the velocity field in a (non-conducting) 3-D channel flow [6]. It also extends to three dimensions our past efforts for the 2-D Hartmann flow [33]. None of these extensions are trivial, since the growing number of states (three components of the velocity field, the electric field and the pressure field, all infinite-dimensional, evolving in an infinite 3-D region) make the problem very challenging.

Our controller is designed for the continuum MHD model. Since the system is spatially invariant [34], control synthesis is done in the wave number space after application of a Fourier transform. Large wave numbers are found to be stable and left uncontrolled whereas for small wave numbers control is used. For these wave numbers, control is used to put the system in a strict-feedback form; this is necessary for application of the backstepping method for stabilization of parabolic PDE's [35]. Writing the velocity field in some appropriate coordinates, the resulting system is very similar to the Orr-Sommerfeld-Squire system of PDE's for non-conducting fluids and presents the same difficulties (non-normality leading to a large transient growth mechanism [36, 37]). Thus, applying the same ideas as in [6], we use backstepping not only to guarantee stability but also to decouple the system in order to prevent transients. The control gains are computed solving a set of linear hyperbolic PDEs—a much simpler task than, for instance, solving nonlinear operator Riccati equations. Actuation of velocity and electric potential is done at only one of the channel walls. Full state knowledge is assumed, but the controller can be combined with an observer for MHD channel flow [32], which is a dual to the controller design in the present paper, to obtain an
The paper is organized as follows. Section 2 introduces the governing equations. The equilibrium profile is presented in Section 3 and the linearized plant in wave number space introduced in Section 4. Section 5 presents the design of the control laws to guarantee stability of the closed-loop system and states the main result. We end the paper with concluding remarks in Section 6.

2 Model

Consider an incompressible conducting fluid enclosed between two plates, separated by a distance $L$, under the influence of a pressure gradient $\nabla P$ and a magnetic field $B_0$ normal to the walls, as shown in Figure 1. Under the assumption of a very small magnetic Reynolds number

$$Re_M = \nu \rho \sigma U_0 L \ll 1,$$  \hspace{1cm} (1)$$

where $\nu$ is the viscosity of the fluid, $\rho$ the density of the fluid, $\sigma$ the conductivity of the fluid, and $U_0$ the reference velocity (maximum velocity of the equilibrium profile), the dynamics
of the magnetic field can be neglected and the dimensionless velocity and electric potential field is governed by the inductionless MHD equations [38].

We set nondimensional coordinates \((x, y, z)\), where \(x\) is the streamwise direction (parallel to the pressure gradient), \(y\) the wall normal direction (parallel to the magnetic field) and \(z\) the spanwise direction, so that \((x, y, z) \in (-\infty, \infty) \times [0, 1] \times (-\infty, \infty)^1\). The governing equations are

\[
U_t = \frac{\Delta U}{Re} - UU_x - VU_y - WU_z - P_x + N\phi_z - NU, \tag{2}
\]

\[
V_t = \frac{\Delta V}{Re} - UV_x - VV_y - WW_z - P_y, \tag{3}
\]

\[
W_t = \frac{\Delta W}{Re} - UW_x - VW_y - WW_z - P_z - N\phi_x - NW, \tag{4}
\]

\[
\Delta \phi = U_z - W_x, \tag{5}
\]

where \(U, V\) and \(W\) denote, respectively, the streamwise, wall-normal and spanwise velocities, \(P\) the pressure, \(\phi\) the electric potential, \(Re = \frac{U_0 L}{\nu}\) is the Reynolds number and \(N = \frac{\sigma LB^2}{\rho U_0}\) the Stuart number. Since the fluid is incompressible, the continuity equation is verified

\[
U_x + V_y + W_z = 0. \tag{6}
\]

The boundary conditions for the velocity field are

\[
U(t, x, 0, z) = 0, \quad U(t, x, 1, z) = U_c(t, x, z), \tag{7}
\]

\[
V(t, x, 0, z) = 0, \quad V(t, x, 1, z) = V_c(t, x, z), \tag{8}
\]

\[
W(t, x, 0, z) = 0, \quad W(t, x, 1, z) = W_c(t, x, z), \tag{9}
\]

\(^1\)Our approach can be extended to finite, periodic channels with only some changes; see e.g. [39] for techniques involved.

Rafael Vazquez
where \( U_c(t,x,z), V_c(t,x,z) \) and \( W_c(t,x,z) \) denote, respectively, the actuators for streamwise, wall-normal and spanwise velocity in the upper wall. We denote the initial conditions for the velocity field as \( U_0(x,y,z) = U(0,x,y,z), V_0(x,y,z) = V(0,x,y,z), W_0(x,y,z) = W(0,x,y,z) \).

Assuming perfectly conducting walls, the electric potential must verify

\[
\phi(t,x,0,z) = 0, \quad \phi(t,x,1,z) = \Phi_c(t,x,z),
\]

(10)

where \( \Phi_c(t,x,z) \) is the imposed potential (electromagnetic actuation) in the upper wall. The nondimensional electric current, \( j(t,x,y,z) \), a vector field that is computed from the electric potential and velocity fields as follows,

\[
j^x(t,x,y,z) = -\phi_x - W,
\]

(11)

\[
j^y(t,x,y,z) = -\phi_y,
\]

(12)

\[
j^z(t,x,y,z) = -\phi_z + U,
\]

(13)

where \( j^x, j^y, \) and \( j^z \) denote the components of \( j \).

We assume that all actuators can be independently actuated for every \((x,z) \in \mathbb{R}^2\). Note that no actuation is done inside the channel or at the bottom wall.

### 3 Equilibrium profile

The equilibrium profile for system (2)–(5) with no control can be calculated following the same steps that yield the Poiseuille solution for Navier-Stokes channel flow. Thus, we assume a steady solution with only one nonzero nondimensional velocity component, \( U^c(y) \), that
depends only on the $y$ coordinate. Substituting $U^e(y)$ in equation (2), one finds that it verifies the following equation,

$$0 = \frac{U_{yy}^e(y)}{Re} - P_x^e - NU^e(y),$$  \hspace{1cm} (14)$$
whose nondimensional solution is, setting $P^e$ such that the maximum velocity (centerline velocity) is unity,

$$U^e(y) = \frac{\sinh(H(1 - y)) - \sinh H + \sinh(Hy)}{2 \sinh H/2 - \sinh H},$$  \hspace{1cm} (15)$$

$$V^e = W^e = \phi^e = 0,$$  \hspace{1cm} (16)$$

$$P^e = \frac{N \sinh H}{2 \sinh H/2 - \sinh H x},$$  \hspace{1cm} (17)$$

$$j^x = j^y = 0, j^z = U^e(y).$$  \hspace{1cm} (18)$$

where $H = \sqrt{ReN} = B_0 L \sqrt{\frac{\sigma}{\rho \nu}}$ is the Hartmann number. In Fig. 2(left) we show $U^e(y)$ for different values of $H$. Since the equilibrium profile is nondimensional the center line velocity is always 1. For $H = 0$ the classic parabolic Poiseuille profile is recovered. In Fig. 2 (right) we show $U^e_y(y)$, proportional to shear stress, whose maximum is reached at the boundaries and grows with $H$.

4 The Plant in Wave Number Space

Define the fluctuation variables

$$u(t, x, y, z) = U(t, x, y, z) - U^e(y),$$  \hspace{1cm} (19)$$

$$p(t, x, y, z) = P(t, x, y, z) - P^e(y)$$  \hspace{1cm} (20)$$

where $U^e(y)$ and $P^e(y)$ are, respectively, the equilibrium velocity and pressure given in (15) and (17). The linearization of (2)–(4) around the Hartmann equilibrium profile, written in Rafael Vazquez DS-08-1170
Figure 2: Streamwise equilibrium velocity $U^e(y)$ (left) and $U^e_y(y)$ (right), for different values of $H$. Solid, $H = 0$; dash-dotted, $H = 10$; dashed, $H = 50$.

the fluctuation variables $(u, V, W, p, \phi)$, is

$$u_t = \frac{\Delta u}{Re} - U^e(y)u_x - U^e_y(y)V - p_x + N\phi_z - Nu, \quad (21)$$

$$V_t = \frac{\Delta V}{Re} - U^e(y)V_x - p_y, \quad (22)$$

$$W_t = \frac{\Delta W}{Re} - U^e(y)W_x - p_z - N\phi_x - NW. \quad (23)$$

The equation for the potential is

$$\Delta \phi = u_z - W_x, \quad (24)$$

and the fluctuation velocity field verifies the continuity equation,

$$u_x + V_y + W_z = 0, \quad (25)$$
and the following boundary conditions

\[ u(t, x, 0, z) = W(t, x, 0, z) = V(t, x, 0, z) = 0, \quad (26) \]

\[ u(t, x, 1, z) = U_c(t, x, z), \quad (27) \]

\[ V(t, x, 1, z) = V_c(t, x, z), \quad (28) \]

\[ W(t, x, 1, z) = W_c(t, x, z), \quad (29) \]

\[ \phi(t, x, 0, z) = 0, \quad \phi(t, x, 1, z) = \Phi_c(t, x, z). \quad (30) \]

We denote the initial conditions for the fluctuation velocity as

\[ u_0(x, y, z) = U_0(x, y, z) - U^e(y). \]

To guarantee stability, our design task is to design feedback laws \( U_c, V_c, W_c \) and \( \Phi_c \), so that the origin of the velocity fluctuation system is exponentially stable. Full state knowledge is assumed.

Since the plant is linear and spatially invariant [34], we use a Fourier transform in the \( x \) and \( z \) coordinates (the spatially invariant directions). The transform pair (direct and inverse transform) is defined for any function \( f(x, y, z) \) as

\[ f(k_x, y, k_z) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y, z)e^{-2\pi i(k_x x + k_z z)} dz dx, \quad (31) \]

\[ f(x, y, z) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(k_x, y, k_z)e^{2\pi i(k_x x + k_z z)} dk_z dk_x. \quad (32) \]

Note that we use the same symbol \( f \) for both the original \( f(x, y, z) \) and the image \( f(k_x, y, k_z) \).

In hydrodynamics \( k_x \) and \( k_z \) are referred to as the “wave numbers.”

Rafael Vazquez  DS-08-1170  11
The plant equations in wave number space are

\[
\begin{align*}
    u_t &= \frac{-\alpha^2 u + u_{yy}}{Re} - \beta(y)u - U_e^e(y)V - 2\pi k_z i p - Nu + 2\pi k_x i N \phi, \\
    V_t &= \frac{-\alpha^2 V + V_{yy}}{Re} - \beta(y)V - p_y, \\
    W_t &= \frac{-\alpha^2 W + W_{yy}}{Re} - \beta(y)W - 2\pi k_z i p - NW - 2\pi k_x i N \phi,
\end{align*}
\]  

(33) (34) (35)

where \( \alpha^2 = 4\pi^2(k_x^2 + k_z^2) \) and \( \beta(y) = 2\pi ik_z U_e^e(y) \).

The continuity equation in wave number space is expressed as

\[
2\pi k_x u + V_y + 2\pi k_z W = 0,
\]

(36)

and the equation for the potential is

\[
-\alpha^2 \phi + \phi_{yy} = 2\pi i (k_z u - k_x W).
\]

(37)

The boundary conditions are

\[
\begin{align*}
    u(t, k_x, 0, k_z) &= W(t, k_x, 0, k_z) = V(t, k_x, 0, k_z) = 0, \\
    u(t, k_x, 1, k_z) &= U_c(t, k_x, k_z), \\
    V(t, k_x, 1, k_z) &= V_c(t, k_x, k_z), \\
    W(t, k_x, 1, k_z) &= W_c(t, k_x, k_z), \\
    \phi(t, k_x, 0, k_z) &= 0, \phi(t, k_x, 1, k_z) = \Phi_c(t, k_x, k_z).
\end{align*}
\]

(38) (39) (40) (41) (42)
5 Control Design

We design the controller in wave number space. Note that (33)–(42) are uncoupled for each wave number. It is well known that large wave numbers (which correspond to small scales where dissipation is present) are already stable and instability can only be found in small wave numbers (large scale behavior) [3]. Therefore, as in [5, 6], the set of wave numbers \( k_x^2 + k_z^2 \leq M^2 \), which we refer to as the controlled wave number range, and the set \( k_x^2 + k_z^2 > M^2 \), the uncontrolled wave number range, can be treated and studied separately. If stability for all wave numbers is established, stability in physical space follows (see [5]).

The number \( M \), which will be computed in Section 5.2, is a parameter that ensures stability for uncontrolled wave numbers.

We define \( \chi \), a truncating function, as

\[
\chi(k_x, k_z) = \begin{cases} 
1, & k_x^2 + k_z^2 \leq M^2, \\
0, & \text{otherwise.} 
\end{cases} 
\]  

(43)

Then, we reflect that we don’t use control for large wave numbers by setting

\[
\begin{pmatrix} 
U_c(t, x, z) \\
V_c(t, x, z) \\
W_c(t, x, z) \\
\Phi_c(t, x, z)
\end{pmatrix} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \begin{pmatrix} 
U_c(t, k_x, k_z) \\
V_c(t, k_x, k_z) \\
W_c(t, k_x, k_z) \\
\Phi_c(t, k_x, k_z)
\end{pmatrix} \times \chi(k_x, k_z) e^{2\pi i (k_x x + k_z z)} dk_z dk_x. 
\]  

(44)

Next we design stabilizing control laws for small wave numbers and analyze uncontrolled wave numbers.

Rafael Vazquez

DS-08-1170
5.1 Controlled wave number analysis

Consider $k_x^2 + k_z^2 \leq M^2$. Then $\chi = 1$, so there is control. Using the continuity equation (36) and taking divergence of (33)–(35), a Poisson equation for the pressure is derived,

$$ -\alpha^2 p + p_{yy} = -4\pi k_x i U_y^c(y) V + NV_y. $$  

(45)

Evaluating equation (34) at $y = 0$ one finds that

$$ p_y(k_x, 0, k_z) = \frac{V_{yy}(k_x, 0, k_z)}{Re} = -2\pi i \frac{k_x u_{y0} + k_z W_{y0}}{Re}, $$

(46)

where we use (36) for expressing $V_{yy}$ at the bottom in terms of $u_{y0} = u_y(k_x, 0, k_z)$ and $W_{y0} = W_y(k_x, 0, k_z)$. Similarly, evaluating equation (34) at $y = 1$ we get

$$ p_y(k_x, 1, k_z) = \frac{V_{yy}(k_x, 1, k_z)}{Re} - (V_c)_t - \alpha^2 \frac{V_c}{Re} $$

$$ = -2\pi i \frac{k_x u_{y1} + k_z W_{y1}}{Re} - (V_c)_t - \alpha^2 \frac{V_c}{Re}, $$

(47)

where we use (36) for expressing $V_{yy}$ at the top wall in terms of $u_{y1} = u_y(k_x, 1, k_z)$ and $W_{y1} = W_y(k_x, 1, k_z)$ and the controller $V_c$.

Equation (45) can be solved in terms of integrals of the state and the boundary terms.
appearing in (46) and (47).

\[
p = -\frac{4\pi k_x i}{\alpha} \int_0^y U^c_y(\eta) \sinh (\alpha(y - \eta)) V(k_x, \eta, k_z) d\eta \\
+ N \int_0^y \frac{\sinh (\alpha(y - \eta))}{\alpha} V_g(k_x, \eta, k_z) d\eta \\
+ 2\pi i \frac{\cosh (\alpha(1 - y))}{\alpha \sinh \alpha} k_x u_{y0} + k_z W_{y0} \\
+ \frac{4\pi k_x i \cosh (\alpha y)}{\alpha \sinh \alpha} \int_0^1 U^c_y(\eta) \cosh (\alpha(1 - \eta)) \\
\times V(k_x, \eta, k_z) d\eta - N \frac{\cosh (\alpha y)}{\alpha \sinh \alpha} \int_0^1 \cosh (\alpha(1 - \eta)) \\
\times V_y(k_x, \eta, k_z) d\eta - 2\pi i \frac{\cosh (\alpha y)}{\alpha \sinh \alpha} \frac{k_x u_{y1} + k_z W_{y1}}{Re} \\
- \frac{\cosh (\alpha y)}{\alpha \sinh \alpha} \left( (V_c)_t + \alpha^2 \frac{V_c}{Re} \right).
\]

(48)

We proceed as in [5] and [6] and use the controller \( V_c \), which appears inside the pressure solution (48), to make the pressure strict-feedback (spatially causal in \( y \)), which is a necessary structure for the application of a backstepping boundary controller [35]. Physically this means that we do not let pressure perturbations of the flow at one given point to be affected by the velocity field closer than the point to the upper wall; only the velocity field “below” the point (closer to the lower wall) can have any affect on the pressure perturbation.

Since the first three lines in (48) are already spatially causal, we need to cancel the fourth, fifth and sixth lines of (48). Set

\[
(V_c)_t = \alpha^2 \frac{V_c}{Re} + 2\pi i \frac{k_x (u_{y0} - u_{y1}) + k_z (W_{y0} - W_{y1})}{Re} \\
+ 4\pi k_x i \int_0^1 U^c_y(\eta) \cosh (\alpha(1 - \eta)) V(k_x, \eta, k_z) d\eta \\
- N \int_0^1 \cosh (\alpha(1 - \eta)) V_y(k_x, \eta, k_z) d\eta,
\]

(49)
which can be written as

\[
(V_c)_t = \alpha^2 \frac{V_c}{Re} + 2\pi i \frac{k_x(u_{y0} - u_{y1}) + k_z(W_{y0} - W_{y1})}{Re} \\
- NV_c + \int_0^1 \cosh (\alpha(1 - \eta)) V(k_x, \eta, k_z) \\
\times (N + 4\pi k_z i U^e(\eta)) \, d\eta.
\] (50)

Then, the pressure is written in terms of a strict-feedback integral of the state \(V\) and the boundary terms \(u_{y0}, W_{y0}\) (proportional to the skin friction at the bottom) as follows

\[
p = -\frac{4\pi k_x i}{\alpha} \int_0^y U^e_y(\eta) \sinh (\alpha(y - \eta)) V(k_x, \eta, k_z) \, d\eta \\
- \frac{2\pi i}{Re} \frac{\cosh (\alpha y) - \cosh (\alpha(1 - y))}{\sinh \alpha} (k_x u_{y0} + k_z W_{y0}) \\
+ N \int_0^y \frac{\sinh (\alpha(y - \eta))}{\alpha} V_y(k_x, \eta, k_z) \, d\eta.
\] (51)

Similarly, solving for \(\phi\) in terms of the control \(\Phi_c\) and the right hand side of its Poisson equation (37),

\[
\phi = \frac{2\pi i}{\alpha} \int_0^y \sinh (\alpha(y - \eta)) \left( k_z u(k_x, \eta, k_z) \\
- k_z W(k_x, \eta, k_z) \right) d\eta + \frac{\sinh (\alpha y)}{\sinh \alpha} \Phi_c(k_x, k_y) \\
- \frac{2\pi i}{\alpha \sinh \alpha} \int_0^1 \sinh (\alpha(1 - \eta)) (k_z u(k_x, \eta, k_z) \\
- k_z W(k_x, \eta, k_z)) \, d\eta.
\] (52)

As in the pressure, an actuator (\(\Phi_c\) in this case) appears inside the solution for the potential. The last two lines of (52) are non-strict-feedback integrals and need to be cancelled to apply the backstepping method. As for the pressure, this means that we do not let electric field perturbations of the flow at one given point to be affected by the velocity field further “up” than the point (closer to the upper wall); only the velocity field closer to the lower wall affects the electrical field perturbation.
For this we use $\Phi_c$ by setting
\[
\Phi_c(k_x, k_y) = \frac{2\pi i}{\alpha} \frac{1}{\int_0^1} \sinh(\alpha(1 - \eta)) \left( k_z u(k_x, \eta, k_z) - k_x W(k_x, \eta, k_z) \right) d\eta.
\]
(53)

Then the potential can then be expressed as a strict-feedback integral of the states $u$ and $W$ as follows
\[
\phi = \frac{2\pi i}{\alpha} \frac{1}{\int_0^y} \sinh(\alpha(y - \eta)) \left( k_z u(k_x, \eta, k_z) - k_x W(k_x, \eta, k_z) \right) d\eta.
\]
(54)

Introducing the expressions (51) and (54) in (33) and (35), we get
\[
u_t = \frac{-\alpha^2 u + u_{yy} - \beta(y) u - U_y^e(y) V - Nu - 4\pi^2 k_x}{Re} \times \frac{\cosh(\alpha y) - \cosh(\alpha(1 - \eta))}{\text{Re} \alpha \sinh \alpha} \left( k_x u_{y0} + k_z W_{y0} \right) - \frac{8\pi k_x^2}{\alpha} \int_0^y U_y^e(\eta) \sinh(\alpha(y - \eta)) V(k_x, \eta, k_z) d\eta - 2\pi i k_z N \int_0^y \frac{\sinh(\alpha(y - \eta))}{\alpha} V_y(k_x, \eta, k_z) d\eta - \frac{4\pi^2 k_x N}{\alpha} \int_0^y \sinh(\alpha(y - \eta)) \times (k_z U(k_x, \eta, k_z) - k_x W(k_x, \eta, k_z)) d\eta,
\]
(55)

\[
W_t = \frac{-\alpha^2 W + W_{yy} - \beta(y) W - NW - 4\pi^2 k_z}{Re} \times \frac{\cosh(\alpha y) - \cosh(\alpha(1 - \eta))}{\text{Re} \alpha \sinh \alpha} \left( k_x u_{y0} + k_z W_{y0} \right) - \frac{8\pi k_x k_z}{\alpha} \int_0^y U_y^e(\eta) \sinh(\alpha(y - \eta)) V(k_x, \eta, k_z) d\eta - 2\pi i k_z N \int_0^y \frac{\sinh(\alpha(y - \eta))}{\alpha} V_y(k_x, \eta, k_z) d\eta + \frac{4\pi^2 k_x N}{\alpha} \int_0^y \sinh(\alpha(y - \eta)) \times (k_z U(k_x, \eta, k_z) - k_x W(k_x, \eta, k_z)) d\eta.
\]
(56)
We have omitted the equation for $V$ since, from (36) and using the fact that $V(k_x, 0, k_z) = 0$, $V$ is computed as

$$V = -2\pi i \int_0^y (k_x U(k_x, \eta, k_z) + k_z W(k_x, \eta, k_z)) d\eta.$$  (57)

Now we use the following change of variables and its inverse,

$$Y = 2\pi i (k_x u + k_z W), \quad \omega = 2\pi i (k_z u - k_x W),$$  (58)

$$u = \frac{2\pi i}{\alpha^2} (k_x Y + k_z \omega), \quad W = \frac{2\pi i}{\alpha^2} (k_z Y - k_x \omega).$$  (59)

Note that $\omega$ is the normal vorticity, whereas $Y = -V_y$, the rate of change of the velocity $V$ along the channel.

Defining $\epsilon = \frac{1}{Re}$ and the following functions

$$g_1 = \frac{4\pi i k_x}{\alpha^2} \left\{ U_y^e(y) - \frac{1}{2} \int_0^y U_y^e(\sigma) \frac{\sinh (\alpha(y - \sigma))}{\alpha} d\sigma \right\} + N\alpha \sinh (\alpha(y - \sigma)),$$  (60)

$$g_2 = \frac{-\alpha \cosh (\alpha y) - \cosh (\alpha(1 - y))}{Re \sinh \alpha},$$  (61)

$$h_1 = 2\pi i k_z U_y^e,$$  (62)

$$h_2 = -N\alpha \sinh (\alpha(y - \sigma)),$$  (63)

equations (55)–(56) expressed in terms of $Y$ and $\omega$ are

$$Y_t = \epsilon (-\alpha^2 Y + Y_{yy}) - \beta(y)Y - NY + gY_0 + \int_0^y f(k_x, y, \eta, k_z) Y(k_x, \eta, k_z) d\eta,$$  (64)

$$\omega_t = \epsilon (-\alpha^2 \omega + \omega_{yy}) - \beta(y)\omega - N\omega + h_1(y) \int_0^y Y(k_x, \eta, k_z) d\eta + \int_0^y h_2(y, \eta) \omega(k_x, \eta, k_z) d\eta.$$

(65)
where we have used the inverse change of variables (59) to express $u_{y0}$ and $W_{y0}$ in terms of $Y_{y0} = Y_y(k_x, 0, k_z)$ as follows

$$Y_{y0} = 2\pi i (k_x u_{y0} + k_z W_{y0}), \quad (66)$$

with boundary conditions

$$Y(t, k_x, 0, k_z) = \omega(t, k_x, 0, k_z) = 0, \quad (67)$$
$$Y(t, k_x, 1, k_z) = Y_c(t, k_x, k_z) \quad (68)$$
$$\omega(t, k_x, 1, k_z) = \omega_c(t, k_x, k_z), \quad (69)$$

where

$$Y_c = 2\pi i (k_z U_c + k_x W_c), \quad \quad \quad \quad \quad (70)$$
$$\omega_c = 2\pi i (k_x U_c - k_z W_c), \quad (71)$$

Equations (64)–(65) are a coupled, strict-feedback plant, with integral and reaction terms. As in [6], a variant of the design presented in [35] can be used to stabilize the system using a double backstepping transformation. The transformation maps, for each $k_x$ and $k_z$, the variables $(Y, \omega)$ into the variables $(\Psi, \Omega)$, that verify the following family of heat equations (parameterized in $k_x, k_z$)

$$\Psi_t = \epsilon \left(-\alpha^2 \Psi + \Psi_{yy}\right) - \beta(y) \Psi - N\Psi, \quad (72)$$
$$\Omega_t = \epsilon \left(-\alpha^2 \Omega + \Omega_{yy}\right) - \beta(y) \Omega - N\Omega, \quad (73)$$

with boundary conditions

$$\Psi(k_x, 0, k_z) = \Psi(k_x, 1, k_z) = 0, \quad (74)$$
$$\Omega(k_x, 0, k_z) = \Omega(k_x, 1, k_z) = 0. \quad (75)$$
The transformation is defined as follows,

\[ \Psi = Y - \int_0^y K(k_x, y, \eta, k_z)Y(k_x, \eta, k_z) d\eta, \]  

(76)

\[ \Omega = \omega - \int_0^y \Gamma_1(k_x, y, \eta, k_z)Y(k_x, \eta, k_z) d\eta - \int_0^y \Gamma_2(k_x, y, \eta, k_z)\omega(k_x, \eta, k_z) d\eta. \]  

(77)

Following [35, 5, 6], the functions \( K(k_x, y, \eta, k_z), \Gamma_1(k_x, y, \eta, k_z), \) and \( \Gamma_2(k_x, y, \eta, k_z) \) are found as the solution of the following partial integro-differential equations,

\[ \epsilon K_{yy} = \epsilon K_{\eta\eta} + (\beta(y) - \beta(\eta)) K - f + \int_\eta^y f(\eta, \xi)K(y, \xi) d\xi, \]  

(78)

\[ \epsilon \Gamma_{1yy} = \epsilon \Gamma_{1\eta\eta} + (\beta(y) - \beta(\eta)) \Gamma_1 - h_1 + \int_\eta^y \Gamma_2(y, \xi) \times h_1(\xi) d\xi + \int_\eta^y f(\eta, \xi)\Gamma_1(y, \xi) d\xi, \]  

(79)

\[ \epsilon \Gamma_{2yy} = \epsilon \Gamma_{2\eta\eta} + (\beta(y) - \beta(\eta)) \Gamma_2 - h_2 + \int_\eta^y h_2(\xi, \eta)\Gamma_2(y, \xi) d\xi. \]  

(80)

Equations (78)–(80) are hyperbolic partial integro-differential equation in the region \( T = \{(y, \eta) : 0 \leq y \leq 1, 0 \leq \eta \leq y\}. \) Their boundary conditions are

\[ K(y, y) = -\frac{g(0)}{\epsilon}, \]  

(81)

\[ K(y, 0) = \frac{\int_0^y K(y, \eta)g(\eta) d\eta - g(y)}{\epsilon}, \]  

(82)

\[ \Gamma_1(y, 0) = \frac{\int_0^y \Gamma_1(y, \eta)g(\eta) d\eta}{\epsilon}, \]  

(83)

\[ \Gamma_1(y, y) = 0, \Gamma_2(y, y) = 0, \Gamma_2(y, 0) = 0. \]  

(84)

**Remark 5.1.** Equations (78)–(84) are well-posed and can be solved symbolically, by means of a successive approximation series, or numerically [35, 6]. Note that (78) and (80) are
autonomous. Hence, one must solve first for $K(k_x, y, \eta, k_z)$ and $\Gamma_2(k_x, y, \eta, k_z)$. Then the solution for $\Gamma_2$ is plugged in Equation 79 which then can be solved for $\Gamma_1(k_x, y, \eta, k_z)$.

Control laws $Y_c$ and $W_c$ are found evaluating (76)–(77) at $y = 1$ and using (68)–(69) and (74)–(75), which yields

$$Y_c(t, k_x, k_z) = \int_0^1 K(k_x, 1, \eta, k_z)Y(k_x, \eta, k_z)d\eta, \quad (85)$$

$$\omega_c(t, k_x, k_z) = \int_0^1 \Gamma_1(k_x, 1, \eta, k_z)Y(k_x, \eta, k_z)d\eta$$
$$+ \int_0^1 \Gamma_2(k_x, 1, \eta, k_z)\omega(k_x, \eta, k_z)d\eta. \quad (86)$$

Using (58)–(59) to write (85)–(86) in $(u, W)$, we get

$$U_c = \int_0^1 K^u(k_x, 1, \eta, k_z)u(k_x, \eta, k_z)d\eta$$
$$+ \int_0^1 K^W(k_x, 1, \eta, k_z)W(k_x, \eta, k_z)d\eta, \quad (87)$$

$$W_c = \int_0^1 K^w(k_x, 1, \eta, k_z)u(k_x, \eta, k_z)d\eta$$
$$+ \int_0^1 K^{ww}(k_x, 1, \eta, k_z)W(k_x, \eta, k_z)d\eta, \quad (88)$$

where

$$\begin{pmatrix}
K^u \\
K^w \\
K^{wu} \\
K^{ww}
\end{pmatrix}
= A
\begin{pmatrix}
K(k_x, y, \eta, k_z) \\
\Gamma_1(k_x, y, \eta, k_z) \\
0 \\
\Gamma_2(k_x, y, \eta, k_z)
\end{pmatrix}, \quad (89)$$
and where the matrix $A$ is defined as

$$A = -\frac{4\pi^2}{\alpha^2} \begin{pmatrix} k_x^2 & k_x k_z & k_x k_z & k_z^2 \\ k_x k_z & k_z^2 & -k_x^2 & -k_x k_z \\ k_x k_z & -k_x^2 & k_z^2 & -k_x k_z \\ k_z^2 & -k_x k_z & -k_x k_z & k_x^2 \end{pmatrix}. \quad (90)$$

Stability in the controlled wave number range follows from stability of (72)–(73) and the invertibility of the transformation (76)–(77). We get the following result, whose proof we sketch (see [6] for more details).

**Proposition 5.1.** For $k_x^2 + k_z^2 \leq M^2$, the equilibrium $u \equiv V \equiv W \equiv 0$ of system (33)–(42) with control laws (50), (53), (87)–(88) is exponentially stable in the $L^2$ norm, i.e.,

$$\int_0^1 (|u|^2 + |V|^2 + |W|^2) (t, k_x, y, k_z) dy \leq C_1 e^{-2\epsilon t} \int_0^1 (|u_0|^2 + |V_0|^2 + |W_0|^2) (0, k_x, y, k_z) dy,$$

where $C_1 \geq 0$.

**Proof.** From equations (72)–(73) we get, using a standard Lyapunov argument,

$$\int_0^1 (|\Psi|^2 + |\Omega|^2) (t, k_x, y, k_z) dy \leq e^{-2\epsilon t} \int_0^1 (|\Psi|^2 + |\Omega|^2) (0, k_x, y, k_z) dy,$$

and then from the transformation (76)–(77) and its inverse (which is guaranteed to exist [35]), we get that

$$\int_0^1 (|Y|^2 + |\omega|^2) (t, k_x, y, k_z) dy \leq C_0 e^{-2\epsilon t} \int_0^1 (|Y|^2 + |\omega|^2) (0, k_x, y, k_z) dy,$$

where $C_0 \geq 0$. 

Rafael Vazquez

DS-08-1170

22
where \( C_0 > 0 \) is a constant depending on the kernels \( K, \Gamma_1 \) and \( \Gamma_2 \) and their inverses. Then writing \( (u,W) \) in terms of \( (Y,\omega) \) and bounding the norm of \( V \) by the norm of \( Y \) (using \( Y = -V_y \) and Poincare’s inequality), the result follows.

### 5.2 Uncontrolled wave number analysis

When \( k_x^2 + k_z^2 > M \), the plant verifies the following equations

\[
\begin{align*}
   u_t & = \frac{-\alpha^2 u + u_{yy}}{Re} - \beta(y) u - U_y^e(y)V - 2\pi k_x i p + 2\pi k_z i N \phi - Nu, \\
   V_t & = \frac{-\alpha^2 V + V_{yy}}{Re} - \beta(y) V - p_y, \\
   W_t & = \frac{-\alpha^2 W + W_{yy}}{Re} - \phi W - 2\pi k_z i p - 2\pi k_x i N \phi - NW,
\end{align*}
\]

(94) \hspace{2cm} (95) \hspace{2cm} (96)

the Poisson equation for the potential

\[
-\alpha^2 \phi + \phi_{yy} = 2\pi i (k_z u - k_x W)
\]

(97)

the continuity equation

\[
2\pi i k_x u + V_y + 2\pi k_x W = 0,
\]

(98)

and Dirichlet boundary conditions

\[
\begin{align*}
   u(t, k_x, 0, k_y) & = V(t, k_x, 0, k_y) = W(t, k_x, 0, k_y) = 0, \\
   u(t, k_x, 1, k_y) & = V(t, k_x, 1, k_y) = W(t, k_x, 1, k_y) = 0, \\
   \phi(t, k_x, 0, k_y) & = \phi(t, k_x, 1, k_y) = 0.
\end{align*}
\]

(99) \hspace{2cm} (100) \hspace{2cm} (101)
Using (58), one gets the following equations for \( Y \) and \( \omega \).

\[
Y_t = \epsilon (-\alpha^2 Y + Y_{yy}) - \beta(y)Y - 2\pi k_x iU_x^e(y)V
+ \alpha^2 p - NY, \tag{102}
\]

\[
\omega_t = \epsilon (-\alpha^2 \omega + \omega_{yy}) - \beta(y)\omega - 2\pi k_z iU_y^e(y)V
- \alpha^2 N\phi - N\omega. \tag{103}
\]

The Poisson equation for the potential is, in terms of \( \omega \),

\[
- \alpha^2 \phi + \phi_{yy} = \omega. \tag{104}
\]

Consider the Lyapunov function

\[
\Lambda = \int_0^1 \frac{|u|^2 + |V|^2 + |W|^2}{2} dy, \tag{105}
\]

where we write \( \int_0^1 f = \int_0^1 f(k_x, y, k_z) dy \). The function \( \Lambda \) is the \( L^2 \) norm (kinetic energy) of the perturbation velocity field (which is closely related to the turbulent kinetic energy).

Denote by \( f^* \) the complex conjugate of \( f \). Substituting \( Y \) and \( \omega \) from (59) into (105), we get

\[
\Lambda = \int_0^1 4\pi^2 \left[ \frac{k_x^2 |Y|^2 + k_z^2 |\omega|^2}{2\alpha^4} + k_x^2 k_z (Y^* \omega + Y \omega^*) + k_z^2 |Y|^2}{2\alpha^4} \right] + \int_0^1 \frac{|V|^2}{2} dy
= \int_0^1 \frac{|Y|^2 + |\omega|^2 + \alpha^2 |V|^2}{2\alpha^2}. \tag{106}
\]

Define then a new Lyapunov function,

\[
\Lambda_1 = \alpha^2 \Lambda = \int_0^1 \frac{|Y|^2 + |\omega|^2 + \alpha^2 |V|^2}{2}. \tag{107}
\]
The time derivative of $\Lambda_1$ can be estimated as follows,

$$\dot{\Lambda}_1 = -2\epsilon\alpha^2\Lambda_1 - \epsilon \int_0^1 (|Y|^2 + |\omega|^2 + \alpha^2|V|^2)$$

$$-N \int_0^1 (|Y|^2 + |\omega|^2) - \alpha^2N \int_0^1 \frac{\phi^*\omega + \phi\omega^*}{2}$$

$$+ \int_0^1 \pi iU^c(y) [V^*(2k_xY + k_z\omega) - V(2k_xY^* + k_z\omega^*)]$$

$$+ \alpha^2 \int_0^1 \frac{P^*Y + PY^* - P^*V - P_yV^*}{2}.$$

(108)

For bounding (108), we use the following two lemmas.

**Lemma 5.1.** $-\alpha^2 \int_0^1 \frac{\phi^*\omega + \phi\omega^*}{2} \leq \int_0^1 |\omega|^2.$

**Proof.** The term we want to estimate is

$$-\alpha^2 \int_0^1 \frac{\phi^*\omega + \phi\omega^*}{2}.$$  

(109)

Substituting $\alpha^2\phi$ from (104), (109) can be written as

$$- \int_0^1 \frac{\phi^*_y\omega + \phi_y\omega^*}{2} + \int_0^1 |\omega|^2.$$  

(110)

Therefore, we need to prove that

$$\int_0^1 (\phi^*_y\omega + \phi_y\omega^*) \geq 0.$$  

(111)

Substituting $\omega$ from equation (104) into (111), we get

$$\int_0^1 (\phi^*_y\omega + \phi_y\omega^*)$$

$$= \int_0^1 |\phi_y|^2 - \alpha^2 \int_0^1 (\phi_y^*\phi + \phi_y\phi^*)$$

$$= \int_0^1 |\phi_y|^2 + \alpha^2 \int_0^1 |\phi|^2,$$  

(112)

which is nonnegative. □

Rafael Vazquez

DS-08-1170
Lemma 5.2. $|U^c_y(y)| \leq 4 + H$. 

Proof. Computing $U^c_y(y)$ from (15),

$$U^c_y(y) = H \frac{\cosh(Hy) - \cosh(H(1-y))}{2 \sinh H/2 - \sinh H}.$$  \hspace{1cm} (113)

Calling $g_1(y) = \cosh(Hy) - \cosh(H(1-y))$, since $g'_1(y) = H (\sinh(Hy) + \sinh(H(1-y)))$ is always positive for $y \in (0, 1)$, the maximum must be in the boundaries. Therefore

$$|U^c_y(y)| \leq g_2(H) = H \frac{\cosh H - 1}{\sinh H - 2 \sinh H/2}.$$  \hspace{1cm} (114)

One can rewrite $g_2$ as

$$g_2 = H \frac{\sinh H/2}{\cosh H/2 - 1}.$$  \hspace{1cm} (115)

Since $g_2(0) = 4$, it suffices to verify that $g'_2(H) \leq 1$.

$$g'_2(H) = \frac{g_3}{g_4} = \frac{\sinh H/2 - H^2/2}{\cosh H/2 - 1}.$$  \hspace{1cm} (116)

This is equivalent to verify that $g_3 \leq g_4$. Since $g_3(0) = g_4(0) = 0$, it is enough that $g'_3 \leq g'_4$, which follows from

$$g'_3 = H/2 (\cosh H/2 - 2H) \leq H/2 (\sinh H/2) = g'_4,$$  \hspace{1cm} (117)

because $\cosh x - 4x \leq \sinh x$. \hfill \Box

Integrating by parts and applying Lemma 5.1,

$$\dot{\Lambda}_1 \leq -2\epsilon \alpha^2 \Lambda_1 - \epsilon \int_0^1 \left( |Y_y|^2 + |\omega_y|^2 + \alpha^2 |V_y|^2 \right)$$

$$+ \int_0^1 \pi i U^c_y(y) V^*(k_x Y + k_z \omega)$$

$$- \int_0^1 \pi i U^c_y(y) V(k_x Y^* + k_z \omega^*) - N \int_0^1 |Y|^2.$$  \hspace{1cm} (118)
Using Lemma 5.2 to bound \( U^c_y \) in (118),

\[
\dot{\Lambda}_1 \leq -2\epsilon (1 + \alpha^2) \Lambda_1 - N \int_0^1 |Y|^2 dy \\
+ 2\pi (4 + H) \int_0^1 (|V|(|k_x||Y| + |k_z||\omega|) dy \\
\leq (4 + H - 2\epsilon (1 + \alpha^2)) \Lambda_1
\]  

(119)

where we have applied Young’s and Poincare’s inequalities. Hence, if \( \alpha^2 \geq \frac{4+H}{2\epsilon} \),

\[
\dot{\Lambda}_1 \leq -2\epsilon \Lambda_1.
\]  

(120)

Dividing (120) by \( \alpha^2 \) and using (107), we get that

\[
\dot{\Lambda} \leq -2\epsilon \Lambda,
\]  

(121)

and stability in the uncontrolled wave number range follows when \( k_x^2 + k_z^2 \geq M^2 \) for \( M \) (conservatively) chosen as

\[
M \geq \frac{1}{2\pi} \sqrt{\frac{(H + 4)Re}{2}}.
\]  

(122)

We summarize the result in the following proposition.

**Proposition 5.2.** For \( k_x^2 + k_z^2 \geq M^2 \) where \( M \geq \frac{1}{2\pi} \sqrt{\frac{(H + 4)Re}{2}} \), the equilibrium \( u \equiv V \equiv W \equiv 0 \) of the uncontrolled system (94)–(101) is exponentially stable in the \( L^2 \) sense, i.e.,

\[
\int_0^1 (|u|^2 + |V|^2 + |W|^2) (t, k_x, y, k_z) dy \\
\leq e^{-2\epsilon t} \int_0^1 (|u_0|^2 + |V_0|^2 + |W_0|^2) (k_x, y, k_z) dy.
\]  

(123)
5.3 Main result

Substituting (50), (53) and (87)–(88) in (44), and using the Fourier convolution theorem, we get the control laws in physical space, which can be expressed compactly as

\[
\begin{pmatrix}
U_c \\
W_c \\
\Phi_c
\end{pmatrix} = \int_{-\infty}^{\infty} \int_{1}^{0} \int_{-\infty}^{\infty} \Sigma(x - \xi, \eta, z - \zeta) \times \begin{pmatrix}
u(\xi, \eta, \zeta) \\
W(\xi, \eta, \zeta)
\end{pmatrix} d\xi d\eta d\zeta,
\]

where

\[
\Sigma(\xi, \eta, \zeta) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \Sigma(k_x, \eta, k_z) \times \chi(k_x, k_z) e^{2\pi i (k_x \xi + k_z \zeta)} dk_z dk_x,
\]

and

\[
\Sigma = \begin{pmatrix}
K^{\text{Vu}}(k_x, 1, \eta, k_z) & K^{\text{VW}}(k_x, 1, \eta, k_z) \\
K^{\text{Wu}}(k_x, 1, \eta, k_z) & K^{\text{WW}}(k_x, 1, \eta, k_z)
\end{pmatrix}
\]

Control law \(V_c\) is a dynamic feedback law computed as the solution of the following forced parabolic equation

\[
(V_c)_t = \frac{(V_c)_{xx} + (V_c)_{zz}}{Re} - NV_c + g(t, x, z),
\]

where \(g(t, x, z)\) is defined as

\[
g = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left[ \int_{0}^{1} g_V(x - \xi, \eta, z - \zeta)V(\xi, \eta, \zeta)d\eta \\
+ g_W(x - \xi, z - \zeta)(W_0(\xi, 0, \zeta) - W_1(\xi, 1, \zeta)) \\
+ g_u(x - \xi, z - \zeta)(u_0(\xi, 0, \zeta) - u_1(\xi, 1, \zeta)) \right] d\xi d\zeta.
\]
and

\[ g_u = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} 2\pi i \frac{k_x}{Re} \chi(k_x, k_z) e^{2\pi i (k_x + k_z) \xi + k_z \zeta} dk_x dk_z, \quad (129) \]

\[ g_V = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \cosh(\alpha(1 - \eta)) \left( N + 4\pi k_x i U_y(\eta) \right) \times \chi(k_x, k_z) e^{2\pi i (k_x + k_z) \xi + k_z \zeta} dk_z dk_x, \quad (130) \]

\[ g_W = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} 2\pi i \frac{k_z}{Re} \chi(k_x, k_z) e^{2\pi i (k_x + k_z) \xi + k_z \zeta} dk_x dk_z. \quad (131) \]

As in [5, 6], considering all wave numbers and using Proposition 5.1 and Proposition 5.2, the following result holds regarding the convergence of the closed-loop system.

**Theorem 1.** Consider the system (21)–(30) with control laws (124)–(131). Then the equilibrium profile \( u \equiv V \equiv W \equiv 0 \) is asymptotically stable in the \( L^2 \) norm, i.e.,

\[
\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (u^2 + V^2 + W^2)(t) dx dy dz \leq C_2 e^{-2\epsilon t} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (u_0^2 + V_0^2 + W_0^2)(x, y, z) dx dy dz. \quad (132)
\]

where \( C_2 = \max\{C_1, 1\} \geq 0 \).

We have assumed in the above result that the closed loop linearized system is well-posed and that the velocity and electromagnetic field equations have at least \( L^2 \) solutions. See [40] for some mathematical considerations on the well-posedness of MHD problems.

**Remark 5.2.** In case that \( N = 0 \), meaning that either there is no imposed magnetic field or the fluid is nonconducting, Equations (2)–(4) are the Navier-Stokes equations. Some physical insight can be gained analyzing this case. In the context of hydrodynamic stability theory, the linearized observer error system written in \( (Y, \omega) \) variables verify equations analogous to the classical Orr-Sommerfeld-Squire equations. These are Equations (64)–(65) for controlled.
wave numbers and Equations (102)–(103) for uncontrolled wave numbers. As in [6], we use the backstepping transformations (76)–(77) not only to stabilize (damping the system using gain $l$) but also to decouple the system (using gains $\Gamma_1$, $\Gamma_2$) in the small wave number range, where non-normality effects are more severe. Even if the linearized system is stable, non-normality produces large transient growths [3, 37], which enhanced by nonlinear effects may allow the system to go far away from the origin, activating the mechanism of transition to turbulence. This warrants the use of extra gains to map the system into two uncoupled heat equations (72)–(73).

**Remark 5.3.** As in [5, Theorem 2], some properties of the feedback control laws can be derived. The most important properties of the feedback laws from the point of view of implementation are the spatial decay of the kernels and conservation of mass. Spatial decay means that the function $\Sigma(x, y, z)$ appearing in (124) rapidly decrease as $x$ or $z$ grow, and that implies that the control law mostly needs information about the states close to the actuation point. This suggest that our control laws could be approximately implemented by an array of discrete actuators, each of them only requiring information only from the flow in its vicinity. Conservation of mass is derived by studying the behavior of the control laws at wave numbers $k_x = k_z = 0$, and can be mathematically expressed as

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} V_c(x, z) dx dz = 0.$$  \hspace{1cm} (133)

Physically, it means that the actuators do not need to add or subtract mass from the flow to stabilize it, which is a very desirable property for a possible implementation.
Figure 3: The chain of transformations used to design the control laws. Note that all transformations are invertible.

\[
\begin{align*}
\{U,V,W,\Psi\}(x,y,z) & \xrightarrow{\text{Subtract equilibrium}} \{u,V_w,p,\phi\}(x,y,z) \\
& \xrightarrow{\text{Fourier transform}} \{u,V_w,p,\phi\}(k_x,y,k_y) \\
& \xrightarrow{\text{Solve the Poisson equation}} \{u,w\}(k_x,y,k_y) \\
& \xrightarrow{\text{Apply } V_x \text{ and } \Phi_x \text{ controllers}} \{Y,\omega\}(k_x,y,k_y) \\
& \xrightarrow{\text{Invertible transformation}} \{\Psi,\Omega\}(k_x,y,k_y)
\end{align*}
\]

6 Concluding Remarks

In this paper we have stabilized the Hartmann flow, a benchmark MHD model with several potential applications. We have used the backstepping method, that allows to compute the control kernels without needing to discretize the system. Our solution is summarized in control laws (124)–(131) and Theorem 1. The feedback kernels given by (89)–(90) and calculated from (78)–(84) can be computed beforehand.

The design of the control laws (124)–(131) was based on using several invertible transfor-
mations to simplify the problem and then go back to obtain the solution in physical space. Fig. 3 summarizes all the transformations that were used. The structure of the controller is shown in Fig. 4 (top).

These feedbacks laws require full-state knowledge. In [32] we presented an observer for estimation of velocity and electromagnetic fields of the Hartmann flow, based on boundary measurement of pressure, current and skin friction. Such an observer can be used together with the control laws (124)–(131) to obtain an output feedback stabilizing boundary controller that only needs boundary measurements; a block diagram showing the structure of the proposed output feedback controller is shown in Fig. 4 (bottom).

This work can be used as the starting point to also solve the problems of motion planning and trajectory tracking, which are of interest in engineering applications. The problem has been solved in the case of non-conducting fluids [41] using the backstepping method.

Our result uses the linear backstepping control method for parabolic PDEs and thus requires linearization of the MHD equations as a first step. Hence, Theorem 1 only holds for initial conditions close enough to the equilibrium profile. If one considers instead the fully nonlinear MHD equations, the problem is extremely challenging not only because of the nonlinearity itself, but also because the plant becomes coupled in the wave number space. The nonlinearity is of bilinear type and recent developments that extend the backstepping method to nonlinear parabolic PDEs using Volterra series [42, 43] and to the viscouse Burgers equation [44, 45] are potentially applicable, however the method has to be extended to consider the coupling between different wave numbers.
